

ABSTRACT

IMPROVEMENTS IN OR RELATING TO WATER FEATURES

A combined water feature and planter is in the form of a rectangular trough formed by a one-piece plastics material hollow moulded shell. A base of the planter has drainage openings therein leading to respective drainage passages which extend through a water reservoir for water recycled through an ornamental pump. The drainage passages are thus isolated from the water reservoir so that liquid draining through the passages to the exterior of the trough does not mix with the water recycling through the pump and cannot thus contaminate it.
